Spindle cell lesions in a synthetic series

First Author, Second Author and Third Author

Abstract

This synthetic abstract describes a small series of spindle cell lesions. The tumours were reviewed by two observers and the results were compared with the immunohistochemical profile of each case.

Spindle cell tumours of soft tissue form a broad group of lesions with overlapping morphology. The tumour cells are arranged in long fascicles and show mild nuclear atypia with rare mitoses. In the second series the cells were stained with eosin and reviewed again by the same observers before the final diagnosis was made.

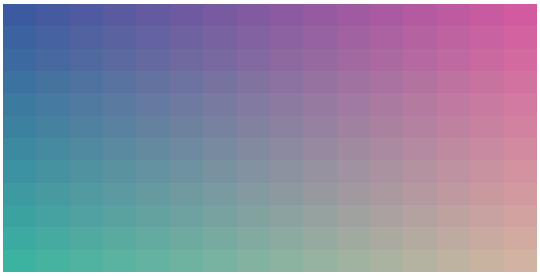

Figure 1. Spindle cells arranged in long fascicles.

Methods

All specimens were fixed in buffered formalin and embedded in paraffin. Sections were cut at four microns.

Marker	Positive	Negative
CD34	12	3
S100 protein	4	11

1 Corresponding author: synthetic address, Example City.

The second page continues the discussion of the series. Most lesions were benign and no tumour recurred.
